

Reduced-Rank Regression Model: A Review

Frances Lin

March 2022

Background and Introduction

A classical multivariate linear model, which is given as

$$Y_k = CX_k + \varepsilon_k, \quad k = 1, \dots, T$$

where $Y_i = (y_{1k}, \dots, y_{mk})^T$ is a $m \times 1$ response vector, C is a $m \times n$ regression coefficient matrix, $X_k = (x_{1k}, \dots, x_{nk})^T$ is a $n \times 1$ predictor vector, and $\varepsilon_k = (\varepsilon_{1k}, \dots, \varepsilon_{mk})^T$ is a $m \times 1$ error vector with $E(\varepsilon_k) = 0$ and $\text{cov}(\varepsilon_k) = \Sigma_{\varepsilon\varepsilon}$, does not make use of the fact that the response variables are likely correlated.

In many practical situations, there is also often a need to reduce the number of parameters in the model.

Introduction

Further assuming lower rank of the matrix C such that

$$\text{rank}(C) = r \leq \min(m, n)$$

lead us to two implications.

1. The linear combination, $I^T Y_k$, $i = 1, \dots, (m - r)$, can be modeled through the distribution of the error term ε_k .
2. C can be expressed as $C = AB$, where A is of dimension $m \times r$ and B is of dimension $r \times n$. Then, the multivariate linear model can be rewritten as

$$Y_k = A(BX_k) + \varepsilon_k, \quad k = 1, \dots, T,$$

where BX_k is of reduced dimension $r \times 1$, and as a result, there is a gain in simplicity and interpretation.

Introduction

The first application of reduced-rank regression model appeared in an initial work of Anderson (1951) in the field of economics. The model and its statistical properties were further examined by a few other authors.

Subsequent but separate work that were studied using related concepts were

- ▶ principle components (Rao, 1964),
- ▶ simultaneous linear prediction modeling (Fortier, 1966),
- ▶ redundancy analysis, an alternative to canonical correlation analysis (van den Wollenberg, 1977), etc.

More complex models have also been developed ever since.

Applications

Applications of the reduced-rank regression model include

- (1) the experimental properties of hydrocarbon fuel mixtures in relating response to composition (Davies and Tso, 1982),
- (2) an econometric model of the United Kingdom from 1948 to 1956 (Gudmundsson, 1977), which consists of 37 time series of response variables and 32 time series of predictors,
- (3) the relationship between measurements on solar radiation taken over various sites in Scotland and the physical characteristics of the sites (Glasbey, 1992), etc,
